Melatonin ELISA Kit

Catalog #: ENZ-KIT150-0001

96-Well Kit
USE FOR RESEARCH PURPOSES ONLY

Unless otherwise specified expressly on the packaging, all products sold hereunder are intended for and may be used for research purposes only and may not be used for food, drug, cosmetic or household use or for the diagnosis or treatment of human beings. Purchase does not include any right or license to use, develop or otherwise exploit these products commercially. Any commercial use, development or exploitation of these products or development using these products without the express written authorization of Enzo Life Sciences, Inc. is strictly prohibited. Buyer assumes all risk and liability for the use and/or results obtained by the use of the products covered by this invoice whether used singularly or in combination with other products.

LIMITED WARRANTY; DISCLAIMER OF WARRANTIES

These products are offered under a limited warranty. The products are guaranteed to meet all appropriate specifications described in the package insert at the time of shipment. Enzo Life Sciences’ sole obligation is to replace the product to the extent of the purchasing price. All claims must be made to Enzo Life Sciences, Inc., within five (5) days of receipt of order. THIS WARRANTY IS EXPRESSLY IN LIEU OF ANY OTHER WARRANTIES OR LIABILITIES, EXPRESS OR IMPLIED, INCLUDING WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF THE PATENT OR OTHER INTELLECTUAL PROPERTY RIGHTS OF OTHERS, AND ALL SUCH WARRANTIES (AND ANY OTHER WARRANTIES IMPLIED BY LAW) ARE EXPRESSLY DISCLAIMED.

TRADEMARKS AND PATENTS

Several Enzo Life Sciences products and product applications are covered by US and foreign patents and patents pending. Enzo is a trademark of Enzo Life Sciences, Inc.

FOR RESEARCH USE ONLY.
NOT FOR USE IN DIAGNOSTIC PROCEDURES.

INTRODUCTION

The Enzo Melatonin ELISA is a complete kit for the determination of melatonin in human, mouse, rat and other sample types. The detection is independent of species, with the use of a simple, rapid extraction protocol. Please read the complete kit insert before performing this assay.

This assay allows for the easy and precise measurement of melatonin in multiple matrices with a rapid time-to-answer. Using this kit, changes in Melatonin levels can be measured in two hours, with a high level of reproducibility, specificity, and accuracy. The levels measured align with published GC / MS data, and the sensitivity of the assay is such that serum and plasma levels can be measured with only a quick extraction. This assay is independent of species, and results have been obtained from animal and fruit matrices. Melatonin (N-acetyl-5-methoxytryptamine) is produced in the pineal gland and is a major component of the regulation of the circadian rhythm. In typical individuals, it is present at higher concentrations during the night, and contributes to the normal sleep-wake cycle.

Melatonin is produced from tryptophan through a number of hydroxylation and methylation steps. It is metabolized in the liver, and excreted in urine as 6-hydroxymelatonin and 6-sulfatoxymelatonin. The Enzo Melatonin ELISA shows no cross reactivity with any of the major melatonin metabolites or precursors.

Melatonin and metabolites of melatonin, have demonstrated antioxidant and free radical scavenging potential. There is also evidence that they play a role in the regulation of reactive oxygen protein pathways. Published research shows a possible correlation to melatonin levels and the prevalence of certain cancers.

Saliva can be used to measure melatonin levels. Saliva, compared to serum or plasma, is relatively easy to obtain and does not contain many of the interfering substances present in serum and plasma. Melatonin in saliva is representative of the levels circulating throughout the body, although the exact proportion is still not fully quantified with published values ranging from 20 – 50% of serum values. New areas of research have grown around studying melatonin and the effect on libido, luteinizing hormone (LH), luteinizing hormone (LH), follicle-stimulating hormone (FSH), and other hormone pathways. The role in cancer, sleep cycle, aging, and other areas are also growing in interest, with particular focus on melatonin receptors and the bioavailability of circulating melatonin with the increased use of melatonin as a dietary supplement. The effect on individuals that work late night shifts, and people with
decreased ability to perceive light, is also of important as normal
day and night cues are not present and the regulation of melatonin
levels is affected.2,6

PRINCIPLE

1. Samples or standards are added to wells coated with a goat
anti-mouse IgG antibody. A monoclonal antibody specific to
free melatonin and a solution of a biotin labeled melatonin
tracer are added to the wells.
2. The plate is incubated. During this incubation, the antibody
binds to melatonin in the sample or to the tracer in a
competitive manner.
3. The plate is washed, leaving only bound melatonin and
bound tracer on the plate. A solution of Horseradish
Peroxidase conjugated Streptavidin (SA-HRP) is added,
which binds to the biotinylated tracer. The plate is then
incubated.
4. Once the incubation is complete, excess SA-HRP is washed
out and TMB substrate solution is added and incubated. An
HRP-catalyzed reaction generates a blue color in the
solution.
5. Stop solution is added to stop the substrate reaction. The
resulting yellow color is read at 450 nm. The amount of
signal is inversely proportional to the level of melatonin in the
sample.
**MATERIALS SUPPLIED**

1. **Goat anti-Mouse IgG Microtiter Plate, One Plate of 96 Wells**  
   **Catalog No. 80-0050**  
   A plate using break-apart strips coated with a goat anti-mouse IgG antibody.

2. **Assay Buffer 10, 50ml**  
   **Catalog No. 80-2735-0050**  
   Tris buffered saline containing detergents.

3. **Melatonin Standard, 5,000ng**  
   **Catalog No. 80-2729-0005**  
   One vial containing 5,000 ng of lyophilized melatonin standard.

4. **Melatonin Tracer (100X), 60µl**  
   **Catalog No. 80-2731-0060**  
   100X concentrated solution of biotin labeled Melatonin tracer.

5. **Melatonin Antibody, Lyophilized**  
   **Catalog No. 80-2728-0100**  
   Lyophilized melatonin monoclonal antibody.

6. **Stabilizer (50X), 1ml**  
   **Catalog No. 80-2732-0001**  
   50X concentrated stabilizer for the addition to standards and samples in Assay Buffer 10 dilutions.

7. **Melatonin Conjugate, 20ml**  
   **Catalog No. 80-2730-0020**  
   A solution of Streptavidin-conjugated Horseradish Peroxidase.

8. **Wash Buffer Concentrate (20X), 25ml**  
   **Catalog No. 80-1286**  
   One bottle containing 20X Tris buffered saline containing detergent.

9. **TMB Substrate, 25ml**  
   **Catalog No. 80-2101**  
   A solution of 3,3’5,5’ tetramethylbenzidine (TMB) and hydrogen peroxide.

10. **Stop Solution 2, 10ml**  
    **Catalog No. 80-0377**  
    A 1N solution of hydrochloric acid in water. Keep tightly capped.  
    Caution: **Caustic**

11. **Clear Plate Sealer, 3 each**  
    **Catalog No. 30-0012**

12. **Melatonin ELISA Assay Layout, 1 each**  
    **Catalog No. 30-0340**

---

**Do not mix components from different kit lots or use reagents beyond the expiration date of the kit.**

**Protect from light**

**Stop solution is caustic. Keep tightly capped.**
STORAGE
All of the components of this kit (except antibody and standard) are stable at 4°C until the kit’s expiration date. The melatonin standard and antibody must be stored at -20°C until the kit’s expiration date. Freeze any unused portions of reconstituted standard and 10X antibody at -20°C. Avoid repeated freeze/thaw cycles.

OTHER MATERIALS NEEDED
1. Deionized or distilled water
2. Precision pipets for volumes between 5µl and 1,000µl
3. Repeater pipet for dispensing volumes between 50µl and 200µl
4. Disposable containers for diluting concentrates, tracer, and antibody solutions.
5. Graduated cylinders
6. A microplate shaker
7. Adsorbent paper for blotting
8. Microplate reader capable of reading at 450 nm
9. Glass tubes for preparing standards and small dilutions.
10. Ethyl Acetate for solution phase extraction of samples.
11. SpeedVac™ (vacuum centrifuge with vapor trap) for drying extracted samples. Alternatively, drying under a stream of inert gas is acceptable.
SAMPLE HANDLING

This assay is suitable for measuring melatonin in a number of matrices. Human, mouse and rat, serum and plasma and porcine serum have been validated for use, but other species may also work. Human saliva, and fruit (banana and plum) have also been validated in this assay. Other matrices, not presented in this manual, should be validated by the researcher using the extraction and assay protocol supplied.

Please refer to the section titled “Sample Matrix Properties” for validation data and minimum required dilution range for matrices confirmed for use with this kit. However, due to variation in samples, further dilution may be required. Users must determine the optimal dilution(s) for their samples and experiments.

The protocol for testing fruit is similar to other samples, but some alterations to the protocol may be required to produce the best extract. Because of the great range in consistency in plant materials, the researcher should use great care in producing the cleanest possible sample for assay. To do this, freezing, freeze drying, sonication, or homogenization in the presence of the 1X Stabilizer may be necessary.

Saliva samples can range in viscosity. It is suggested that the investigator take great care in collection and storage of saliva samples. A general protocol for the clean capture of saliva suitable for assay is provided.

SERUM / PLASMA EXTRACTION

Many sample types will contain materials that will interfere with accurate determination of melatonin levels. It is recommended that all samples be extracted using the protocol provided. Extraction also provides a way to concentrate matrices with low levels of melatonin.

The solution phase extraction protocol provided uses Ethyl Acetate, followed by reconstitution in 1X Stabilizer. Using this procedure you can concentrate up to 750µl of sample up to 7-fold. The level of enrichment is dependent on the sample and the requirements of the researcher.

Solution Phase Extraction of Melatonin

1. Add sample (i.e. Serum, plasma, saliva) to tube.
   a. Make sure all precipitates and solids have been removed by centrifugation prior to addition. For serum and plasma, a 1000g spin for 5 – 10 minutes at 4 °C is sufficient.
b. Add an equal volume of cold Ethyl Acetate (typical extraction is between 500 – 750µl sample and 500 – 750µl Ethyl Acetate).

2. Vortex gently. Allow layers to separate on ice, in a covered ice bucket for three minutes. Vortex once more and incubate on ice for two minutes.

3. Spin at 1000g for 10 minutes at 4°C.

4. Carefully remove the organic layer to a new tube.

   For Ethyl Acetate this will be the top layer, with a fairly solid interface, with the aqueous portion on the bottom. It is better to remove less with higher purity than to contaminate the sample with aqueous or interface material. Remove as much as you can without contamination, usually 95% of the original volume.

5. Use a SpeedVac™, with condenser, apply no heat, and dry the sample completely. The dried extract will be a clear to off-white pellet. Some color may be present in certain samples (some fruits, or serums). If no SpeedVac™ is available, drying under a stream of inert gas is acceptable.

6. Suspend the pellet in 100 - 250µl of 1X Stabilizer

   As an example, with a starting volume of 750µl (with 700µl removed for purity margin), and a suspension volume of 100µl, so sample has been concentrated 7-fold. Be sure to include any enrichment factor in your calculations.

7. If samples are to be assayed immediately, keep on ice after suspension and perform assay. Dried samples can be stored at -20 degrees for a month. Once suspended, assay the sample as soon as possible, if needed, freeze the suspended sample at -20 degrees, and assay within one week.

8. Treat all samples and standards similarly when using extracted samples to account for any extraction and reconstitution loss.

   Prepare an extracted standard curve to establish absolute values, or use a non-extracted curve if you wish to compare values of samples relative to each other.
SALIVA COLLECTION & EXTRACTION

The following is a recommended protocol for collecting and processing saliva samples for use in the assay.

**Note:** Do not eat or drink anything with dyes or color 30 minutes prior to collection as this may affect results. Collect under dimmest possible lighting, as light can have a marked effect on melatonin levels.

Saliva Collection Protocol

1. Rinse mouth 3 times with water.
2. Place collection tube to mouth and let saliva pool in the mouth. Salivary production can be stimulated by chewing on parafilm or dental wax.
3. Let the pooled saliva flow into the tube by gravity. Do not forcibly propel saliva into tube as this increases viscosity and additional mouth proteins that can interfere with the assay.
4. When at least 0.5 – 1 ml has been collected, cap the tube and protect from light. Keep the solution frozen or on ice until time to assay.
5. If samples are to be assayed within a few days, short term storage at 4 °C in glass tubes (protected from light) should be acceptable. Longer term storage should be by freezing at -20 °C in glass tubes.
6. If samples are overly viscous, vortex, and spin at 1000g for 3 -5 minutes. If sample is still too viscous, recollection may be required.
7. Once the saliva is frozen and thawed, assay as soon as possible. Saliva contains melatonin at a level that is approximately 20 - 50% of serum levels. Saliva can be collected easily, and simplifies measurements at multiple time points.
8. Some saliva samples (base levels, day time levels or typical low phase), will have too little melatonin to be measured. For these samples it is necessary to extract and concentrate to a higher degree than samples collected during the night.
9. For consistency of results, it is suggested that the researcher extracts all saliva samples with Ethyl Acetate prior to assay. This will allow for more accurate control, and longer storage of the sample.

See Appendix I, for sample saliva time course experiment.
FRUIT SAMPLE EXTRACTION & DATA

For assaying fruit, the preparation of a well extracted homogenate is required. The protocol below works well for softer fruits (bananas, plums, cherries, etc.). Harder fruits, or more fibrous plant materials, may require sonication, liquid nitrogen freezing or freeze drying and suspension to create a proper sample for ELISA.

1. Weigh out 500mg of fruit, or an amount that occupies approximately 500µl of space.
2. Add 125µl of 1X Stabilizer, and use a mini pestle to homogenize to a smooth consistency.
3. Add an equal volume (approximately 750µl) of cold Ethyl Acetate and vortex. Use mini pestle if needed to homogenize further.
4. Set sample on ice for 3 minutes. Vortex again, and incubate on ice an additional 2 minutes, then spin at 1000g for 10 minutes.
5. Remove the organic layer to a fresh tube and dry to completeness.
6. Store dry pellet at -20 degrees until needed, or proceed directly to assay.
7. To assay, suspend pellet in 125 - 250µl of 1X Stabilizer, and assay at least two dilutions, in duplicate, to make sure that your sample values are in the range of the assay.

Using this protocol bananas and red plums were assayed. The results are presented in the table below along with published values acquired using RIA, HPLC and GC/MS methods.

<table>
<thead>

* Results for typical values for fruit were obtained from data published in Hattori, et al. 1995, Dubbels, et al, 1995 and Burkhardt et al., 2001.

SAMPLE MATRIX PROPERTIES

Linearity

Extracted serum and EDTA plasma samples, saliva, and fruit were serially diluted 1:2 in 1X Stabilizer. Samples were run in the assay and compared to the standard curve.
### Spike and Recovery

Purified melatonin was spiked at three concentrations into the minimum recommended dilution of human, rat, mouse, porcine and fruit matrices. Matrix background was subtracted from the spiked values and the average percent recovery for each matrix at the minimum required dilution is presented below. These results show the tested matrices at the minimum recommended dilution have no obvious interference with the Melatonin ELISA assay.

</table>
Parallelism

To assess parallelism, human serum and EDTA plasma samples, human saliva, porcine along with other matrix samples were serially diluted in 1X Stabilizer. The samples were then run in the assay. The melatonin concentration in each sample was determined from the standard curve. Concentrations were plotted as a function of sample dilution. Parallelism of the curves demonstrates that the standard binding characteristics are similar enough to allow the accurate determination of native melatonin levels in diluted samples matrices of animal and plant origin.
REAGENT PREPARATION

NOTE: ALL SAMPLE AND STANDARD DILUTIONS SHOULD BE PREPARED IN GLASS. ANTIBODY AND TRACER DILUTIONS CAN PREPARED IN POLYPROPYLENE.

1. **1X Stabilizer Solution**
   For use in Sample/Standard Dilutions
   Dilute the 50X Stabilizer Solution to 1X in Assay Buffer 10 to create the 1X Stabilizer. This solution should be made fresh for each assay run and is used to reconstitute the lyophilized standard and for preparing the standard curve dilutions. It is also needed for the suspension and dilution of all samples. To prepare 5ml of 1X Stabilizer, dilute 100µl of 50X Stabilizer into 4900 µl of Assay Buffer 10.

2. **Wash Buffer**
   Prepare the Wash Buffer by diluting 25ml of the supplied concentrate with 475ml of deionized water. This can be stored at room temperature until the kit expiration, or for 3 months, whichever is earlier.

3. **Melatonin Standard Curve**
   Suspend the lyophilized Standard by adding 1ml of 1X Stabilizer to the vial. Vortex, and store on ice until needed. The suspended standard is 5,000 ng/ml of Melatonin. To prepare the standard curve, dilute the 5000 ng/ml stock, 1:100 to create the first point, 50ng/ml, then perform 5-fold serial dilutions for 4 additional points.

   Standard curve preparation:
   1. Label 5 glass tubes 1-5.
   2. To tube 1 add 1980 µL of 1X Stabilizer, to tubes 2 -5 add 400µl of 1X Stabilizer.
   3. Transfer 20µl of reconstituted standard (5,000ng/ml) to tube #1, this is your 50 ng/ml standard.
   4. Mix tube #1, and with a new tip, transfer 100µl to tube #2. This is 100 µl plus 400µl 1X Stabilizer, or a 1:5 dilution. The final concentration is 10 ng/ml.
   5. Mix tube #2, and with a new pipet tip, transfer 100µl, to tube #3. Repeat this for tubes 4 and 5.
A diagram of the dilution series is presented below

Diluted standards should be used within 60 minutes of preparation. Discard any unused standard dilutions.

4. **Melatonin Tracer**

Dilute the 100X Tracer to 1X in Assay Buffer 10, vortex briefly, and place on ice until needed. Do not reuse diluted tracer solutions, prepare fresh daily. Store the unused 100X concentrate at 4°C.

5. **Melatonin Antibody**

Reconstitute the lyophilized melatonin antibody in 600µl Assay Buffer 10 to create a 10X solution. Dilute to 1X in Assay Buffer 10 before running the assay. Store the unused reconstituted 10X concentrate at -20°C. It is stable for 3 freeze-thaw cycles.

**ASSAY PROCEDURE**

Refer to the Assay Layout Sheet to determine the number of wells to be used. Remove unneeded wells and return them, with the desiccant, to the plate bag and seal. Store the unused strips in the original bag at 4°C.

1. Add 100µl of the 1X Stabilizer to the B0 (0 ng/ml standard) wells and 150µl to the NSB wells.
2. Add 100µl of standards #1 through #5 into the appropriate wells.
3. Add 100µl of the samples into the appropriate wells.
4. Add 50µl of the 1X melatonin tracer to all wells except for the blank.
5. Add 50µl of the 1X melatonin antibody to all wells except for the NSB and blank.

6. Seal with plate sealer and incubate at room temperature (RT) on a plate shaker for 1 hour at ~500rpm*. See note.

7. Empty the contents of the wells and wash by adding full well volume, ~ 400µl, of wash solution. Repeat the wash 2 more times for a total of 3 washes. After the final wash, empty or aspirate the wells and firmly tap the plate on a lint free paper towel to remove any remaining wash buffer.

8. Add 200µl of the melatonin conjugate solution to each well except the blank.

9. Seal the plate and incubate at room temperature on a plate shaker for 30 minutes at ~500rpm*.

10. Wash as above (Step 7).

11. Add 200µl of TMB substrate solution into each well. Seal the plate and incubate for 30 minutes at RT on a plate shaker at ~500rpm*.

12. Add 50µl of the stop solution into each well.

13. After zeroing the plate reader against the blank, read optical density at 450 nm. If the plate reader is not capable of adjusting for the blank, manually subtract the mean OD of the substrate blank from all readings.

* The plate shaker speed was based on a BellCo Mini Orbital Shaker (mod no. 7744-08096). The actual speed of the plate shaker should be such that the liquid in the plate wells mixes thoroughly, but does not splash out of the well.
CALCULATION OF RESULTS

The concentration of melatonin can be calculated as follows:

1. Calculate the average net OD for each standard and sample by subtracting the average NSB OD from the average OD for each standard and sample.

   \[
   \text{Average Net OD} = \text{Average OD} - \text{Average NSB OD}
   \]

2. Using data analysis software, plot the Average Net OD for each standard versus melatonin concentration in each standard. We recommend that the data be handled by a software package utilizing a 4 parameter logistic (4PL) curve fitting program.

   Samples with concentrations outside of the standard curve range will need to be reanalyzed using alternative dilution.

PERFORMANCE CHARACTERISTICS

Specificity

The specificity of the assay was determined by assay of potential cross reactants in the kit at a concentration multiple logs higher than the high standard and then measuring in the assay. The cross reactivity is designated as the amount calculated divided by the amount in the assay.

Sensitivity

The sensitivity or limit of detection of the assay is 162 pg/mL. This was determined by interpolation at 2 standard deviations away from the net OD of a total of 20 zero standard replicates. Data was collected from 12 standard curves.

Intra-assay precision was determined by assaying 20 replicates of two controls containing Melatonin in a single assay.

APPENDIX I: 
SALIVA SAMPLE DATA

The data presented below is from a single individual, collected using the protocol above, and assayed using the Enzo Melatonin ELISA. The resulting data was graphed and fit to a 4 parameter curve. The amounts present at each time point were extrapolated, adjusted for dilution and plotted versus time. The amount of melatonin can vary greatly among individuals, and this is one example that demonstrates how changes over time can be measured using this ELISA. This data should not be interpreted as a typical salivary melatonin level, as many environmental, dietary, and personal factors will affect the level measured.

This experiment shows the normal rise and fall of melatonin levels during the course of the day, and this kit’s ability to measure the biological relevant amounts.
